**Abstract**

The study included (20) adult male Swiss albino mice Balb/ C, they were randomly divided into four groups: The first was injected intra peritoneal with 300 mg / kg body weight (B.W.) of paracetamol which considered as low toxic dose, followed by 0.3 ml of normal saline(0.9 % w/v) was administrated orally . Second, mice administrated orally with 0.3 ml of crude traditional oil of *Nigella sativa*, then injected intra peritoneal with 0.3 ml of normal saline(0.9 % w/v). Third, mice injected intra peritoneal with 300 mg / kg (B.W.) of paracetamol , then administrated orally with 0.3 ml of crude traditional oil of *Nigella sativa*. Fourth the control group, mice injected intra peritoneal with with 0.3 ml of normal saline (0.9 % w/v), then administrated orally again with 0.3 ml of normal saline.

The experimental time of treatment were 24 hours for all groups , then all animals were sacrificed , the reproductive organs were dissected out for weighing then preserved in Bouins fixative for histopath.

Statistical analysis showed a significant increase ( P< 0.05) in the value of GPT ( 0.043 ± 0.017) /IU , in the mice treated with 300 mg /kg (B.W) of low toxic dose of paracetamol in compare with control and other treated groups . Also, there is a significant increase ( P< 0.05) in the weight of seminal vesicle ( 0.213 ± 0.058 )/gm in mice administrated with 0.3 ml of crude oil of *Nigella sativa* as compare with control and other treated groups .

Mice group administrated with 0.3 ml of crude oil *Nigella sativa* revealed highly significant increase in sperm count (336 ± 100.17 * 10^4) sperm /mm³ at (P <0.01 ) as compared with control and other treated groups .

Histometry of reproductive organs, revealed a significant increase ( P<0.05) in the wall thickness of testicular seminiferous tubules (66 ± 26.8)/µ in mice administrated with 0.3 ml of crude oil *Nigella sativa* , in contrast to control group and other treatments . Whereas ,the diameter of seminiferous tubules and the height of glandular epithelia of seminal vesicle never be affected either by the administration of crude oil of *Nigella sativa* nor with the injection of 300 mg /kg (B.W) of low toxic dose of paracetamol.

The weights of right and left testis and prostate gland never be affected with all treatments that included in the current study.

The Phytotherapeutic Effect of Traditional Crude Oil of *Nigella sativa* on Male Reproductive System of Albino Mice Treated with Low Toxic Dose of Paracetamol

Nigella sativa, is a genus of about 25 species of small prostrate annual herbaceous, dicotyledons plants in the family Ranunculaceae, native to southern Europe, North Africa and South west Asia. The plant grow to 20-90 cm tall, with finely divided leaves. The leaf segments narrowly linear to thread like, the flowers are delicate with yellow, pink, pale, blue or pale purple, with 5-10 petals, the fruit is a capsule composed of several united follicles each containing numerous seeds [1, 2].

Nigella sativa has been used traditionally for medicinal purposes, both as herb and pressed into oil for a variety of conditions and treatments related to respiratory health, stomach, intestinal health, kidney and liver function [3-5].

Seeds contain numerous esters of structural unusual unsaturated fatty acids with terpen alcohol; traces of alkaloid are found which belong to two different types: isochinoline alkaloids are represented by nigellimine and nigellimine- N-oxide and pyrazol alkaloids include nigilldin and nigellicin [3].

In the essential oil, thymoquinone was identified as the main component and significant amount of fatty acid ethyl esters. On storage, thymoquinone yields dithymoquinone and higher digocondensation products. The seeds also contain a fatty oil rich in unsaturated fatty acids (linoleic acid, oleic acid and dihomolinoleic ) and saturated fatty acids (palmitic and stearic acid) [6,7].

The aqueous extracts of Nigella sativa have increased spermatogenesis of male albino rats at primary and secondary spermatocyte stages the elevation of spermatozoa number as well as the elevation of the secretory activities of accessory glands [8].

Histopathological observations showed that Nigella sativa significantly preserved visceral organ architecture changes induced by various toxic chemicals [9], and this antidotes protection have been primarily attributed to their radical scavenger ability and inactivation of oxidative stress induced by different toxic chemicals therefore, Nigella sativa seeds were used since ancient time in treating natural killer and in treating patients suffering from liver cirrhosis and hepato cellular damage [10 - 12].

The present study was designed to find out the role of phyotherapeutic agent of Nigella sativa on the male reproductive system of mice treated with the low toxic dose of paracetamol.
Paracetamol, is also known as acetaminophen-N-acetyl-p-aminophenol (APAP), is considered to be a safe analgesic and antipyretic agent taken in the therapeutic dose [13]. In overdose, it can cause hepatic and different other organs damage, and this is invariably followed by recovery with the early administration of intravenous N-acetylcysteine or oral methionine (NAC) which considered as antidote [14,15].

The toxic dose of APAP with a single acute ingestion is 150 mg / kg, its rapidly absorbed from the stomach and small intestine and metabolized by conjugation in the liver to nontoxic agents, which are eliminated by urine.

In paracetamol treated mice, shrinkage of the seminiferous tubules and disturbance of regular arrangement of the spermatogenic cells in the testis were observed i.e: the spermatogenic cells were not arranged in contact regular layer as in the case of the normal [16]. Also, [17] studied the long term effect of aspirin on the rat testis and found that aspirin caused significant histological damage and concluded that the disturbed spermatogenesis may be due to the inhibition by aspirin of prostaglandin synthesis that is necessary for the completion of spermatogenesis.

The antidote to APAP poisoning (NAC), a precursor of glutathione, which in addition to increasing glutathione un metabolized APAP, NAC. Function as an antioxidant and also has indirect vasodialatory effect by increasing local nitric oxide(NO) concentrations. The vasodialatory effect on microcirculation enhances local oxygen deliver to peripheral tissues, and thus decreases morbidity and mortality even in established hepatocyte [18].

Acetaminophen toxicity may result from a single toxic dose, from ingestion of large doses of acetaminophen (e.g., 7.5 – 10) gm daily for (1-2 day). [19,20]

Paracetamol, is non prescription drug commonly used for antipyresis and analgesic [21]. It contains a phenol ring, as does oestradiol and an acetyl group as does progesterone, these structural features suggest that paracetamol may possess sex steroid agonist or antagonist activity. Indeed, Uterine, ovarian and testicular atrophy has been reported in mice fed with high doses of paracetamol [22] these observation indicate a possible anti gonadotrophic effect of paracetamol. Further, it is now known that paracetamol come inhibit nitric oxide generation [23], which is essential for normal reproductive activity in the male rat [24].

Paracetamol also has a mild inhibitory action on prostaglandin synthesis in peripheral tissues [25]. In high doses (500-1000 mg/kg) impair fertility on male rats [26]. These observations raise the possibility that long-term use of high doses of paracetamol may interrupt normal reproductive function duo to its antigonadotrophic activity [27].

**Materials and Methods**

**Animals:** (20) adult male Swiss albino mice of Balb/c strain, weighing (27-36 gm) with an age 8 weeks were purchased from Iraqi Center for Drug Research/ Baghdad, these animals were housed during the period of experiment in the animal house unit in medicine college of Babylon University, under controlled temperature of (21 ± 1 C°) and (12 hours) light, (12 hours) darkness schedule, food and water were available *ad libitum.*

**Crude Nigella sativa oil**: crude oil were purchased traditionaly from the local market in Hilla city, this oil was administered orally to mice using animal feeding intubations needles.
Paracetamol (Hyamol): 375 mg/5 ml ampoule (the experimental dose used in the current study was 300 mg/kg (body weight) prepared by: Dr. Azhar Abdul-Hafudh (M.Sc. Pharmacology), Dentistry college, Babylon University).

Experimental Design: - Fasted mice were randomly distributed into four groups, each group contains 5 animals, and as the follows table:-

<table>
<thead>
<tr>

Then all animals were sacrificed under light ether anesthesia after 24 hours of treatment, the reproductive organs were taken out, trimmed free of fat, each organ was weighed separately on electronic balance. The reproductive organs taken into account for study include. Right and left testis, right and left epididymis, prostate gland and seminal vesicle, all these organs were preserved in Bouins fixative for histological studies and histometry.

Sperm count: - Left epididymis was minced in 2 ml of physiological saline then add one drop of eosin (1% solution), the mixed sample was applied to a Neubaures counting chamber under cover slip as the method in [28] 

Histometry: - Slides were prepared according to Persnel and Schreebman [29]. Microscopic measurements of seminiferous tubules diameter, thickness of its wall (spermatogenic layer) and the height of seminal vesicle epithelia was done by using the ocular micrometer after its calibration with stage micrometer and for different magnifications.

Statistical analysis: - All data were subjected to a one-way analysis of variance (ANOVA) to determine the level of significance between control and the treated groups. The significance was tested by finding LSD. Data are reported here as mean ± standard deviation (±SD). [30].

Results
1- Weight of reproductive organs:

The results in (table 1) show a significant increase ( P< 0.05) in the weight of right and left epididymis (0.043 ± 0.017 , 0.042 ± 0.006 )/gm in sequence, in the mice treated with 300 mg/kg (B.W) of low toxic dose of paracetamol in compare with control and other treated groups. Also, there is a significant increase (P<0.05) in the weight of seminal vesicle (0.213 ± 0.058 )/gm in mice administrated with 0.3 ml of crude oil of *Nigella sativa* as compare with control and other treated groups.

The weights of right and left testis and ventral prostate never be affected in all treatments that included in the present study.
2- Sperm count: Mice group administered with 0.3 ml of crude oil *Negilla sativa* revealed highly significant increase in sperm count \((336 \pm 100.17 \times 10^4)\) sperm /mm\(^3\) at \((P < 0.01)\) as compared with control and other treated groups (table 1). 

3- Histometry of reproductive organs: Statistical analysis of data in (table 2) revealed a significant increase \((P<0.05)\) in the wall thickness of testicular seminiferous tubules \((66 \pm 26.8)/\mu\) in mice administrated with 0.3 ml of crude oil *Negilla sativa*, in contrast to control group and other treatments. Whereas, the diameter of seminiferous tubules and the height of glandular epithelia of seminal vesicle never be affected either by the administration of crude oil of *Negilla sativa* nor with the injection of 300 mg /kg (B.W) of low toxic dose of paracetamol.

Table 1 The effect of the injection of (300mg/kg) paracetamol and administration of crude oil of *Negilla sativa* (alone and together) on the weight of male reproductive organs and sperm count in albino mice.

Discussion

Paracetamol is principally metabolized in the liver through two major hepatic routes: glucuronidation and sulphation , the latter route can be rapidly saturated at doses above therapeutic doses, then elimination by dose – dependent formation of glucouro- and sulpho-conjugate derivatives [19 , 20], and this may be the reason of why not all of the organs affected by the treatment of low toxic dose (300 mg/kg) of paracetamol ,such as: testis , prostate and seminal vesicle ,where they need more time to exposed to the tested dose before the elimination process take place, while in regards to epididymis weight, the results show a significant increase that may be due to the abnormal production of free radicals that attack cell components, then lead to damage of some cell macromolecules, proteins ,lipids and nucleic acid which in turn may cause a vacoulation, infiltration and aggregation of fluids and fat ,then increasing their weight [31 , 32].

Inspite of the structural features of paracetamol which possess the phenol ring and acetyl group that suggested the sex steroidal (oestradiol and progesterone) agonist or antagonist [22].

The results related to sperm count revealed no significant differences and the explanation due to the spermatogenic process duration time which requires (53 days ) out which spermatozoa spends last (6-7days) in the final transit through epididymis [33],while the drug spend little time then eliminated as derivatives through urine which mean it need more time to exposed to the therapeutic dose of the drug to expressed the steroidal actions before the elimination process take place.

In contrast, the administration of crude oil of Negilla sativa causes a significant increase in the weight of seminal vesicle, wall thickness of testicular seminiferous tubules and the sperm number, in spite of short exposed period to the extract , this may explain on the bases of the
activity of oil components on the enzyme of oxidative phosphorylation [34], whereas, [35] confirmed that the antifertility activity of Negilla sativa in male rats has been established shown by an inhibition of spermatogenesis and a significant reduction in sialic acid content of the testis, epididymis, seminal vesicle and prostate gland.

These results agree with those of the study of [36,37] whom they found that Negilla sativa ingestion produce increase effects on fertility and reproductive system in adult rats raised from the increase in the accessory glands weights and in the pattern of testosterone secretion. The data regards with the histometry of reproductive organs further confirm the androgen dependent increment. Rajesh and Howard [38] found that, the possible mechanism of the chemopreventive actions of thymoquinon was suggested to be the result of its antioxidant and anti-inflammatory activities coupled with an enhancement of detoxification process which lead to preserve visceral organ architecture changes induced by various toxic chemicals (such as paracetamol that used in present study) and UV-radiation as in histopathological observation [9], this may be a propable reason for the result of mice group that treated with low toxic dose of paracetamol then administrated with crude oil of Negilla sativa which its mechanism of action dissimilar to that of most classic cytotoxic chemo-therapeutic agents [39]
